

Correspondence: Compartment Mapping to Container Mapping

Source feature: Compartment Mapping

Target feature(s): Container Mapping

Automation type: FullAutomation - EASY

Relation: A GMF Compartment Mapping and a Sirius Container Mapping serve the same core purpose: they define a nested graphical container inside a node, used to visually group and structurally contain child elements. Since Sirius does not have a separate “compartment” concept independent of containers, a Container Mapping is the most direct target feature that preserves the compartment’s role as a host region with an internal hierarchy.

Main Strategy:

1. [A] take the parent top node or child reference (A) of the compartment mapping
2. [A] take A's equivalent container mapping (B)
3. [A] create a new container mapping (C) as a child of B
4. [A] write 'aql:iself' into the semantic candidate's expression of C

Strategies of subcorrespondences

Computing Domain Class

1. [A] copy the element feature of A's equivalent node mapping and paste it into domain class

Computing Id

1. [A] take the figure (D) of the visual representation compartment feature
2. [A] copy the name of D and paste it into id

Structural overview
