

Correspondence: Computing Dia Element Width and Height

Source feature: Size
Target feature(s): width, height
Automation type: FullAutomation - COMPLEX
Relation: Both features are responsible for fixing the concrete spatial extent of a node. GMF Size captures dimensional constraints (preferred, minimum, or maximum) at the figure-definition level. JointJS expresses the same intent more directly by as signing explicit width and height values to Dia Elements. Size constraints defined in GMF can be preserved as explicit geometric properties in the JointJS model.

Main Strategy:

1. [A] take Dx (A) and Dy (B) of size (preferred/min/max in order)
2. [A] take the parent shape (C) of size
3. [A] check if C has a figure descriptor parent (X)
4. [-] if X it true
 - 4.1. [A] take the figure descriptor parent (D)
 - 4.2. [A] take the node (E) that refers to D in its figure property
 - 4.3. [A] take all the node mappings (F) that refer to E in their diagram node feature
 - 4.4. [A] take all the equivalent Dia Elements (G) of F
 - 4.5. [A] paste A and B into width and height of the Visual Attributes of G
