

Correspondence: Multiple Label Mappings to Label

Source feature: Feature Label Mapping
Target feature(s):
Automation type: NoDirectMapping -
Relation: GMF Feature Label Mappings and Sirius Label Expressions both serve the same fundamental purpose: defining how semantic attributes are transformed into textual labels on diagram elements. However, GMF supports multiple independent label mappings per node, while Sirius enforces a single label expression per graphical element. This structural mismatch necessitates an approximation rather than a direct mapping.

Operators: Mr. X

Rationale: Because Sirius supports only one style - and consequently one label expression - per diagram element, all GMF Feature Label Mappings associated with the same node are merged into a single AQL expression. Line breaks are used to preserve label separation and readability.

Possible approximations (if any): Label Expression (EASY, MIX)

Main Strategy:

- [A] take all the label mapping siblings (A)
- [A] take the immediate top node/child reference (B) of A
- [A] take the B's equivalent container/node mapping (B)
- [A] take or create a new (if not already exist) style (C) for B and write: "aql:" in the label expression property (D) of C
- [A] for every label mapping (E) in A
 - [A] take the features to display property (F) of E
 - [A] append self.F + '\n' to D
- [M] supervisors should inspect if it matches the structural and visual expectation. if not, they can follow Figure to Style Correspondence

Structural overview
